DEC $140 B$ Representation Learning Lecture 11 | Part 1
Linear Limitations

## Linear Predictors

- Last time, we saw linear prediction functions:

$$
\begin{aligned}
H(\vec{x} ; \vec{w}) & =w_{0}+w_{1} x_{1}+\ldots+w_{d} x_{d} \\
& =\operatorname{Aug}(\vec{x}) \cdot \vec{w}
\end{aligned}
$$

## Linear Decision Functions

$\Rightarrow$ A linear prediction function $H$ outputs a number.

- What if classes are +1 and -1 ?
- Can be turned into a decision function by taking:

$$
\operatorname{sign}(H(\vec{x}))
$$

- Decision boundary is where $H=0$
$\downarrow$ Where the sign switches from positive to negative.

## Decision Boundaries

- A linear decision function's decision boundary is linear.
- A line, plane, hyperplane, etc.

## An Example: Parking Predictor

- Task: Predict (yes / no): Is there parking available at UCSD right now?
- What training data to collect? What features?

## Useful Features

- Time of day?
- Day's high temperature?

## Exercise

Imagine a scatter plot of the training data with the two features:

- $x_{1}=$ time of day
- $x_{2}=$ temperature
"yes" examples are green, "no" are red.
What does it look like?

## Parking Data

## Uh oh

- A linear decision function won't work.

What do we do?

## Today's Question

How do we learn non-linear patterns using linear prediction functions?

DST $140 B$
Representation Learning Lecture 11 | Part 2
Feature Maps

## Representations

- We represented the data with two features: time and temperature
- In this representation, the trend is nonlinear.
$\Rightarrow$ There is no good linear decision function
> Learning is "difficult".

## Idea

- Idea: We'll make a new representation by creating new features from the old features.
- The "right" representation makes the problem easy again.
- What new features should we create?

## New Feature Representation

- Linear prediction functions ${ }^{1}$ work well when relationship is linear
- When $x$ is small we should predict -1
$\Rightarrow$ When $x$ is large we should predict +1
- But parking's relationship with time is not linear:
- When time is small we should predict +1
- When time is medium we should predict -1
- When time is large we should predict +1

[^0]
## Exercise

How can we "transform" the time of day $x_{1}$ to create a new feature $x_{1}^{\prime}$ satisfying:

- When $x_{1}^{\prime}$ is small, we should predict -1

When $x_{1}^{\prime}$ is large, we should predict +1
What about the temperature, $x_{2}$ ?

## Idea

- Transform "time" to "absolute time until/since Noon"
- Transform "temp." to "absolute difference between temp. and 72"

## Basis Functions

- We will transform:
$>$ the time, $x_{1}$, to $\mid x_{1}$ - Noon $\mid$
- the temperature, $x_{2}$, to $\left|x_{2}-72^{\circ}\right|$
- Formally, we've designed non-linear basis functions:

$$
\begin{aligned}
& \varphi_{1}\left(x_{1}, x_{2}\right)=\mid x_{1}-\text { Noon } \mid \\
& \varphi_{2}\left(x_{1}, x_{2}\right)=\left|x_{2}-72^{\circ}\right|
\end{aligned}
$$

$\downarrow$ In general a basis function $\varphi$ maps $\mathbb{R}^{d} \rightarrow \mathbb{R}$

## Feature Mapping

- Define $\vec{\varphi}(\vec{x})=\left(\varphi_{1}(\vec{x}), \varphi_{2}(\vec{x})\right)^{T} . \vec{\varphi}$ is a feature map
$>$ Input: vector in "old" representation
> Output: vector in "new" representation
- Example:

$$
\vec{\varphi}\left(\left(10 \mathrm{a} . \mathrm{m} ., 75^{\circ}\right)^{\top}\right)=\left(2 \text { hours, } 3^{\circ}\right)^{\top}
$$

- $\vec{\varphi}$ maps raw data to a feature space.

## Feature Space, Visualized

## Exercise

Where does $\vec{\varphi}$ map $\vec{x}^{(1)}, \vec{x}^{(2)}$, and $\vec{x}^{(3)}$ ?

## Solution

## After the Mapping

- The basis functions $\varphi_{1}, \varphi_{2}$ give us our "new" features.
- This gives us a new representation.
- In this representation, learning (classification) is easier.

## Training

- Map each training example $\vec{x}^{(i)}$ to feature space, creating new training data:

$$
\vec{z}^{(1)}=\vec{\varphi}\left(\vec{x}^{(1)}\right), \quad \vec{z}^{(2)}=\vec{\varphi}\left(\vec{x}^{(2)}\right), \quad \ldots, \quad \vec{z}^{(n)}=\vec{\varphi}\left(\vec{x}^{(n)}\right)
$$

- Fit linear prediction function $H$ in usual way:

$$
H_{f}(\vec{z})=w_{0}+w_{1} z_{1}+w_{2} z_{2}+\ldots+w_{d} z_{d}
$$

## Training Data in Feature Space

## Prediction

If we have $\vec{z}$ in feature space, prediction is:

$$
H_{f}(\vec{z})=w_{0}+w_{1} z_{1}+w_{2} z_{2}+\ldots+w_{d} z_{d}
$$

## Prediction

- But if we have $\vec{x}$ from original space, we must "convert" $\vec{x}$ to feature space first:

$$
\begin{aligned}
H(\vec{x}) & =H_{f}(\vec{\varphi}(\vec{x})) \\
& =H_{f}\left(\left(\varphi_{1}(\vec{x}), \varphi_{2}(\vec{x}), \ldots, \varphi_{d}(\vec{x})\right)^{T}\right) \\
& =w_{0}+w_{1} \varphi_{1}(\vec{x})+w_{2} \varphi_{2}(\vec{x})+\ldots+w_{d} \varphi_{d}(\vec{x})
\end{aligned}
$$

## Overview: Feature Mapping

- A basis function can involve any/all of the original features:

$$
\varphi_{3}(\vec{x})=x_{1} \cdot x_{2}
$$

- We can make more basis functions than original features:

$$
\vec{\varphi}(\vec{x})=\left(\varphi_{1}(\vec{x}), \varphi_{2}(\vec{x}), \varphi_{3}(\vec{x})\right)^{\top}
$$

## Overview: Feature Mapping

1. Start with data in original space, $\mathbb{R}^{d}$.
2. Choose some basis functions, $\varphi_{1}, \varphi_{2}, \ldots, \varphi_{d^{\prime}}$
3. Map each data point to feature space $\mathbb{R}^{d^{\prime}}$ :

$$
\vec{x} \mapsto\left(\varphi_{1}(\vec{x}), \varphi_{2}(\vec{x}), \ldots, \varphi_{d^{\prime}}(\vec{x})\right)^{t}
$$

4. Fit linear prediction function in new space:

$$
H(\vec{x})=w_{0}+w_{1} \varphi_{1}(\vec{x})+w_{2} \varphi_{2}(\vec{x})
$$

$$
H(\vec{x})=w_{0}+w_{1} \varphi_{1}(\vec{x})+w_{2} \varphi_{2}(\vec{x})
$$

## Today's Question

- Q: How do we learn non-linear patterns using linear prediction functions?
- A: Use non-linear basis functions to map to a feature space.

DEC $140 B$ Representation Learning Lecture 11 | Part 3
Basis Functions and Regression

## By the way...

- You've (probably) seen basis functions used before.
- Linear regression for non-linear patterns in DSC 40A.

## Example

## Fitting Non-Linear Patterns

- Fit function of the form

$$
H(x)=w_{0}+w_{1} x+w_{2} x^{2}+w_{3} x^{3}+w_{4} x^{4}
$$

- Linear function of $\vec{w}$, non-linear function of $x$.

## The Trick

- Treat $x, x^{2}, x^{3}, x^{4}$ as new features.
- Create design matrix:

$$
x=\left(\begin{array}{ccccc}
1 & x_{1} & x_{1}^{2} & x_{1}^{3} & x_{1}^{4} \\
1 & x_{2} & x_{2}^{2} & x_{2}^{3} & x_{2}^{4} \\
\vdots & \vdots & \vdots & \vdots & \vdots \\
1 & x_{n} & x_{n}^{2} & x_{n}^{3} & x_{n}^{4}
\end{array}\right)
$$

- Solve $X^{\top} X \vec{w}=X^{\top} \vec{w}$ for $\vec{w}$, as usual.
- Works for more than just polynomials.

## Another View

- We have changed the representation of a point:

$$
x \mapsto\left(x, x^{2}, x^{3}, x^{4}\right)
$$

- Basis functions:

$$
\varphi_{1}(x)=x \quad \varphi_{2}(x)=x^{2} \quad \varphi_{3}(x)=x^{3} \quad \varphi_{4}(x)=x^{4}
$$

DEC $140 B$
Representation Learning Lecture 11 Part 4
A Tale of Two Spaces

## A Tale of Two Spaces

- The original space: where the raw data lies.
- The feature space: where the data lies after feature mapping $\vec{\varphi}$
- Remember: we fit a linear prediction function in the feature space.

## Exercise

- In feature space, what does the decision boundary look like?
- What does the prediction function surface look like?

## Decision Boundary in Feature Space ${ }^{2}$

${ }^{2}$ Fit by minimizing square loss

## Prediction Surface in Feature Space

## Exercise

- In the original space, what does the decision boundary look like?
- What does the prediction function surface look like?

## Decision Boundary in Original Space ${ }^{3}$

${ }^{3}$ Fit by minimizing square loss

## Prediction Surface in Original Space

time

## Insight

$-H$ is a sum of basis functions, $\varphi_{1}$ and $\varphi_{2}$.

$$
H(\vec{x})=w_{0}+w_{1} \varphi_{1}(\vec{x})+w_{2} \varphi_{2}(\vec{x})
$$

- The prediction surface is a sum of other surfaces.
- Each basis function is a "building block".

# Visualizing the Basis Function $\varphi_{1}$ 

$w_{0}+w_{1} \mid x_{1}-$ noon $\mid$

## Visualizing the Basis Function $\varphi_{2}$

$\Rightarrow w_{0}+w_{2}\left|x_{2}-72^{\circ}\right|$

## Visualizing the Prediction Surface

## View: Function Approximation

- Find a function that is $\approx 1$ near green points and $\approx-1$ near red points.

## What's Wrong?

- We've discovered how to learn non-linear patterns using linear prediction functions.
- Use non-linear basis functions to map to a feature space.
- Something should bug you, though...

[^0]:    ${ }^{1}$ Remember: they are weighted votes.
