

Problem 2

SPRING 24 FINAL

Michelle and Abel are each touring apartments for where they might live next year.

Michelle wants to be close to UCSD so she can attend classes easily. Abel is graduating and wants to live close to the beach so he can surf. Each person makes their own DataFrame (called `michelle` and `abel` respectively), to keep track of all the apartments that they toured. Both `michelle` and `abel` came from querying `apts`, so both DataFrames have the same columns and structure as `apts`.

Here are some details about the apartments they toured.

- Michelle toured **one bedroom and studio** apartments at 12 different complexes, or 24 apartments total.
- Abel toured **one bedroom and two bedroom** apartments at 20 different complexes, or 40 apartments total.
- There are 8 complexes that are near both UCSD and the beach, and both Michelle and Abel toured these complexes.

We'll assume for this problem only that there is just one apartment of each size available at each complex, so that if they both tour a one bedroom apartment at the same complex, it is the exact same apartment with the same `"Apartment ID"`.

Problem 2.1

What does the following expression evaluate to?

```
michelle.merge(abel, left_index=True, right_index=True).shape[0]
```

[Click to view the solution.](#)

Problem 2.2

What does the following expression evaluate to?

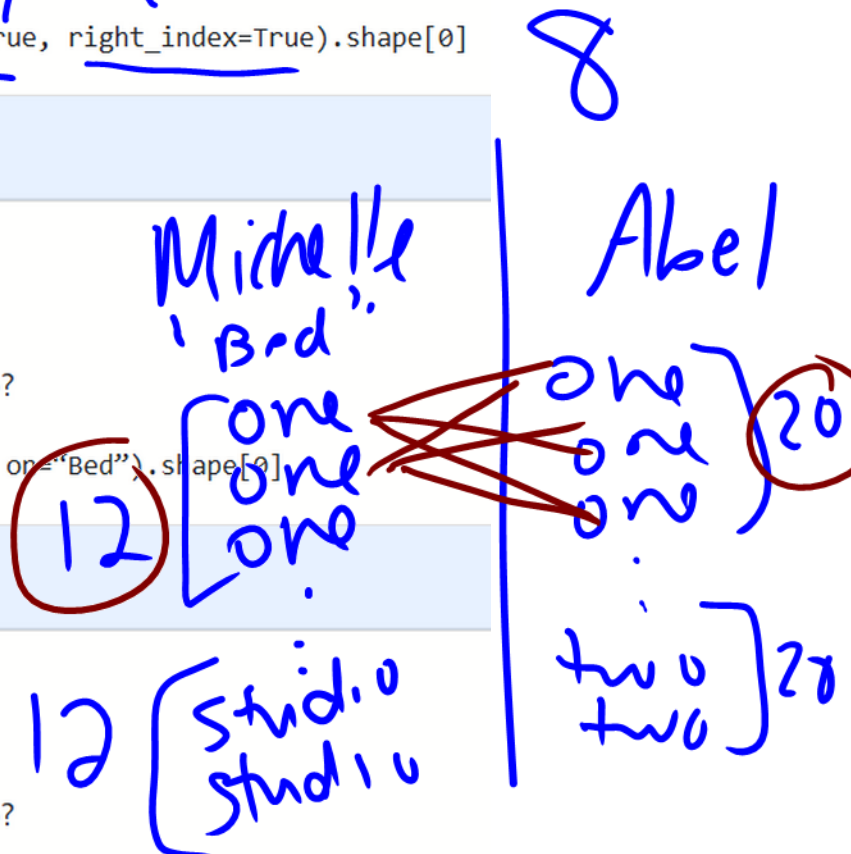

```
michelle.merge(abel, on="Bed").shape[0]
```

[Click to view the solution.](#)

Problem 2.3

What does the following expression evaluate to?

12 * 20

Problem 2.3

What does the following expression evaluate to?

```
michelle.merge(abel, on="Complex").shape[0]
```

4 * 8
matches per complex

complexes merged df has four rows with A

Michelle
"Complex"

Abel
"Complex"

Click to view the solution.

Problem 2.4

What does the following expression evaluate to?

```
abel.merge(abel, on="Bed").shape[0]
```

Click to view the solution.

"Bed"
Abel

"Bed"
Abel

8 letters in both dfs

one } 20
one }
one }

one } 20
one }
one }

40 * 20
rows matches per row

two } 20
two }

two } 20
two }

20 * 20 ones + 20 * 20 twos

more / harder practice:
try Q9 on Wi24 Final

reject null vs.
fail to reject null

observed value is unlike those from simulation

dist generated from null through simulation

usually reject null
- depends on direction -
is it in the direction of alt?

Q: is our coin fair or biased towards Heads?

alt

Simulation: flip coin 400, keep track of # Heads

if very few heads, fail to reject null

lots of Heads, more than simulation, reject null, extreme in the direction of alt \Rightarrow reject null, otherwise don't
