Lecture 02 | Part 2 Linear Models

## Last Time: Nearest Neighbors

- Nearest neighbor methods are simple; can work well.
- However, they:
  - 1. "memorize" the training data (inefficient);
  - 2. do not learn relative important of features.

# **Example: Predicting Salary**

- Goal: predict a data scientist's salary from three features:
  - >  $x_1$ : years of experience
  - $x_2$ : # of interview questions missed
  - $\blacktriangleright$   $x_3$ : favorite number

#### Observations:

- x<sub>1</sub> is **positively** associated with salary
- $x_2$  is **negatively** associated with salary
- $x_3$  is **not** associated with salary

# **Prediction Functions**

- Informally: we think years of experience, etc., are predictive of salary.
- Formally: we think there is a function *H* that takes  $\vec{x} = (x_1, x_2, x_3)$  and outputs a good prediction of salary.

 $H(\vec{x}) \rightarrow \text{prediction}$ 

H is called a prediction function.<sup>1</sup>

<sup>&</sup>lt;sup>1</sup>Or, sometimes, a hypothesis function

## **Prediction Functions**

- **Goal:** find an accurate prediction function.
- What should our prediction function look like?
- That is, we must choose a model.
   In context of prediction functions: a hypothesis class.

## **Occam's Razor**

Occam's Razor: when faced with two competing explanations (models), favor the simpler one.<sup>2</sup>

<sup>2</sup>As long as it works, of course.

# **Linear Functions**

- Idea: model salary as a weighted sum of factors.
- ► That is, as a **linear function**:

$$H(\vec{x}) = w_0 + w_1 x_1 + w_2 x_2 + w_3 x_3$$

- $\blacktriangleright$   $w_0, w_1, \dots, w_3$  are the **parameters** or **weights**.
- **TODO:** how do we choose the weights?

#### Exercise

Recall:  $W_0 =$   $x_1$ : years of experience  $W_1 = 5000$   $x_2$ : # of interview questions missed  $W_2 = 1000$  $x_3$ : favorite number  $W_3 = 0$ 

What are reasonable values of the weights in the linear prediction function  $H(\vec{x}) = w_0 + w_1x_1 + w_2x_2 + w_3x_3$  if it is to be a good predictor of salary?

#### **Parameter Vectors**

The parameters of a linear function can be packaged into a parameter vector,  $\vec{w}$ .

**Example:** if 
$$H(\vec{x}) = w_0 + w_1 x_1 + w_2 x_2 + w_3 x_3$$
 then  $\vec{w} = (w_0, ..., w_3)^T$ .

## Parameterization

A linear function  $H(\vec{x})$  is **completely determined** by its parameter vector.

• Can work either with the function, *H*, or vector,  $\vec{w}$ .

Sometimes write  $H(\vec{x}; \vec{w})$ .

## **Number of Parameters**

If a linear predictor H(x; w) takes in d-dimensional feature vectors, it has d + 1 parameters.

$$H(\vec{x}; \vec{w}) = w_0 + w_1 x_1 + w_2 x_2 + \dots + w_d x_d$$
$$= w_0 + \sum_{i=1}^d w_i x_i$$

▶ That is, if  $\vec{x} \in \mathbb{R}^d$ , then  $\vec{w} \in \mathbb{R}^{d+1}$ .

## Visualization

Linear prediction rules have linear graphs.<sup>3</sup>

**Example:** A linear prediction function for salary.

 $H_1(\vec{x}) = \$50,000 + (experience) \times \$8,000$ INDE 100K Salary q0 ¥ 90K 0 70K 601 experience <sup>3</sup>When visualized in feature space.

# **Visualization** (*d* > 1)

- The surface of a prediction function H is made by plotting  $H(\vec{x})$  for all  $\vec{x}$ .
- ▶ If *H* is a linear prediction function, and
  - ▶  $\vec{x} \in R^1$ , then H(x) is a straight line.
  - ▶  $\vec{x} \in \mathbb{R}^2$ , then  $H(\vec{x})$  is a plane.
  - ▶  $\vec{x} \in \mathbb{R}^d$ , then  $H(\vec{x})$  is a *d*-dimensional hyperplane.

### **Note: Compact Form**

Recall the **dot product** of vectors  $\vec{a}$  and  $\vec{b}$ :

$$\vec{a} = (a_1, a_2, ..., a_d)^T$$
  $\vec{b} = (b_1, b_2, ..., b_d)^T$   
 $\vec{a} \cdot \vec{b} = a_1 b_1 + a_2 b_2 + ... + a_d b_d$ 

Observe:

$$H(\vec{x}; \vec{w}) = w_0 + w_1 x_1 + \dots + w_d x_d$$
  
=  $\underbrace{(w_0, w_1, \dots, w_d)^T}_{\vec{w}} \cdot \underbrace{(1, x_1, \dots, x_d)^T}_?$ 

## **Note: Compact Form**

The augmented feature vector Aug(x) is the vector obtained by adding a 1 to the front of x:

$$\vec{x} = \begin{pmatrix} x_1 \\ x_2 \\ \vdots \\ x_d \end{pmatrix} \quad \text{Aug}(\vec{x}) = \begin{pmatrix} 1 \\ x_1 \\ x_2 \\ \vdots \\ x_d \end{pmatrix}$$

With augmentation, we can write:

$$H(\vec{x}) = w_0 + w_1 x_1 + w_2 x_2 + ... + w_d x_d$$
  
=  $\vec{w} \cdot \text{Aug}(\vec{x})$ 

## **Classification?**

We have been focusing on regression.

Linear prediction functions can be used for classification, too.

We will come back to this.

Lecture 02 | Part 3

**Empirical Risk Minimization** 

# **Picking a Prediction Function**

Suppose we model salary as a linear function:

$$H(\vec{x};\vec{w}) = w_0 + w_1 x_1 + w_2 x_2 + x_3 x_3$$

Question: how do we choose weights w<sub>0</sub>, ..., w<sub>3</sub> so that H makes good predictions?

# Learning

- **Assumption:** the future will look like the past.
- If so, we should pick a prediction function that worked well on past data.
- That is, we should learn a function from data.

### Example

# **Training Data**

- ► To learn, we gather training data.
- A set  $\mathcal{D}$  of *n* pairs:  $(\vec{x}^{(i)}, y_i)$   $\vec{x}^{(i)}$  is the *i*th feature vector  $y_i$  is its label (the correct answer)
- In regression, y<sub>i</sub> is a continuous number; in classification, it is discrete.
- This regime is called supervised learning.

## **An Optimization Problem**

- Some prediction functions "fit" the data better than others.
- Idea: find the function that "fits best"

# **Quantifying Fit**

- How do we measure "fit"?
- Formally: measure difference between our prediction  $H(\vec{x}^{(i)})$  and the "right answer",  $y_i$ .
- A loss function quantifies how wrong a single prediction is.
- **Example:** the **absolute loss**  $\ell_{abs}(H(\vec{x}^{(i)}), y_i) = |H(\vec{x}^{(i)}) y_i|$

# **Quantifying Overall Fit**

- Idea: a good H makes good predictions on average over entire data set.
- Find H minimizing the expected loss, also called the empirical risk:

$$R(H) = \prod_{i=1}^{n} \ell(H(\vec{x}^{(i)}), y_i)$$

Note: *R* depends on both *H* and the data!

# **Empirical Risk Minimization**

This strategy is called empirical risk minimization (ERM).

- Step 1: choose a hypothesis class
   Let's assume we've chosen linear predictors
- Step 2: choose a loss function
- Step 3: minimize expected loss (empirical risk)

# **ERM for Regression**

- ▶ We have chosen as our hypothesis class the set of **linear functions**  $\mathbb{R}^d \to \mathbb{R}$ .
- Suppose we choose **absolute loss**:

$$\ell_{abs}(H(\vec{x}^{(i)}), y_i) = |H(\vec{x}^{(i)}) - y_i|$$

**Goal:** find *H* minimizing **mean absolute error**:

$$R_{abs}(H) = \sum_{i=1}^{n} |H(\vec{x}^{(i)}) - y_i|$$

# Minimizing Mean Absolute Error

- ▶ **Goal:** out of all **linear** functions  $\mathbb{R}^d \to \mathbb{R}$ , find the function  $H^*$  with the smallest mean absolute error on the training set.
- ► That is, find:

$$H^* = \underset{\text{linear } H}{\operatorname{arg min}} \frac{1}{n} \sum_{i=1}^{n} |H(x_i) - y_i|$$

## Minimizing Mean Absolute Error

Assume for now that d = 1 (one feature). Then  $w \in \mathbb{R}^2$  and:

$$H(x;\vec{w}) = w_0 + w_1 x$$

- Recall that H is completely determined by  $w_0, w_1$ .
- Equivalent goal: find  $w_0$  and  $w_1$  minimizing

$$\frac{1}{n} \sum_{i=1}^{n} |H(x; w_0, w_1) - y_i|$$

# Minimizing Mean Absolute Error

- ► To find optimal  $w_0$  and  $w_1$ , might use calculus. ► Set  $\partial R / \partial w_0 = 0$  and  $\partial R / \partial w_1 = 0$  and solve.
- Problem: absolute value is not differentiable!
- It is hard to minimize the mean absolute error.<sup>4</sup>
- What can we do?

<sup>&</sup>lt;sup>4</sup>Though it can be done with linear programming.

## Minimizing Mean Squared Error

► The **square loss** *is* differentiable:

$$\ell_{sq}(H(\vec{x}), y) = (H(\vec{x}) - y)^2$$

Let's try minimizing the mean squared error instead.

#### Main Idea

We often choose a loss function out of practical considerations.

Lecture 02 Part 4

**Minimizing the MSE** 

# **Our Goal**

- Out of all linear functions ℝ → ℝ, find the function H\* with the smallest mean squared error.
- ► That is, find:

$$H^* = \underset{\text{linear } H}{\operatorname{arg min}} \frac{1}{n} \sum_{i=1}^{n} (H(x_i) - y_i)^2$$

This problem is called least squares regression.

#### For now...

For simplicity, assume that there is only one feature (predictor variable).

- $\vdash H(x; \dot{\vec{w}}) = w_0 + w_1 x$
- I.e., one-dimensional linear regression.
- We will come back to multi-dimensional case in the next lecture.

# Minimizing the MSE

The MSE is a function of a function:

$$R_{sq}(H) = \frac{1}{n} \sum_{i=1}^{n} (H(x_i) - y_i)^2$$

But since H is linear,  $H(x) = w_1 x + w_0$ .

$$R_{sq}(w_1, w_0) = \frac{1}{n} \sum_{i=1}^{n} \left( (w_1 x_i + w_0) - y_i \right)^2$$

Now it's a function of  $w_1, w_0$ .

## **Updated Goal**

Find slope w<sub>1</sub> and intercept w<sub>0</sub> which minimize the MSE, R<sub>sq</sub>(w<sub>1</sub>, w<sub>0</sub>):

$$R_{sq}(w_1, w_0) = \frac{1}{n} \sum_{i=1}^{n} \left( (w_1 x_i + w_0) - y_i \right)^2$$

Strategy: multivariate calculus.

#### Exercise

Suppose we plotted  $R_{sq}(w_1, w_0)$ . What would it look like?  $w W_i^2 + \beta W_2^2 + \cdots$   $R_{sq}(w_1, w_0) = \frac{1}{n} \sum_{i=1}^n ((w_1 x_i + w_0) - y_i)^2$   $\triangleright$  Can  $R_{sq}$  be negative? **no**   $\triangleright$  Can it be zero? **yes** in **Heavy**  $\triangleright$  How many minima / maxima?

#### Answer

## **Recall: the gradient**

If f(x, y) is a function of two variables, the gradient of f at the point (x<sub>0</sub>, y<sub>0</sub>) is a vector of partial derivatives:

$$\nabla f(x_0, y_0) = \begin{pmatrix} \frac{\partial f}{\partial x}(x_0) \\ \\ \frac{\partial f}{\partial y}(y_0) \end{pmatrix}$$

**Key Fact**: gradient is zero at critical points.

# Strategy

To minimize  $R(w_1, w_0)$ : compute the gradient, set equal to zero, solve.

$$R_{sq}(w_{1},w_{0}) = \frac{1}{n} \sum_{i=1}^{n} \left( (w_{1}x_{i}+w_{0})-y_{i} \right)^{2} \qquad \frac{d}{du} g(f(w)) = g'(f(w))$$

$$\frac{\partial R_{sq}}{\partial w_{1}} = \frac{\partial}{\partial w}, \quad \frac{1}{n} \sum_{i=1}^{n} \left( (w_{i}x_{i}+w_{0})-y_{i} \right)^{2}$$

$$= \frac{1}{n} \sum_{i=1}^{n} \frac{\partial}{\partial w_{i}} \left( (w_{i}x_{i}+w_{0})-y_{i} \right)^{2}$$

$$= \frac{1}{n} \sum_{i=1}^{n} 2 \left( (w_{i}x_{i}+w_{0})-y_{i} \right) \frac{\partial}{\partial w_{i}} \left( (w_{i}x_{i}+w_{0})-y_{i} \right)$$

$$= \frac{2}{n} \sum_{i=1}^{n} \left( (w_{i}x_{i}+w_{0})-y_{i} \right) \times i$$

$$R_{sq}(w_{1},w_{0}) = \frac{1}{n} \sum_{i=1}^{n} \left( (w_{1}x_{i}+w_{0})-y_{i} \right)^{2}$$

$$\frac{\partial R_{sq}}{\partial w_{0}} = \frac{\partial}{\partial w_{0}} \frac{1}{n} \sum \left( \left( w_{1}x_{1}+w_{0} \right)-y_{1} \right)^{2} \right)^{2}$$

$$= \frac{1}{n} \sum 2 \left( \left( w_{1}x_{1}+w_{0} \right) + y_{1} \right) \frac{\partial}{\partial w_{0}} \left( \left( w_{1}x_{1}+w_{0} \right)-y_{1} \right)^{2} \right)^{2}$$

 $= \frac{2}{n} \sum_{i=1}^{n} \left( \left( W_{i} \times_{i}^{i} + W_{o} \right) - y_{i} \right)$ 

# Strategy

$$0 = \frac{2}{n} \sum_{i=1}^{n} \left( (w_1 x_i + w_0) - y_i \right) x_i \quad 0 = \frac{2}{n} \sum_{i=1}^{n} \left( (w_1 x_i + w_0) - y_i \right)$$

- 1. Solve for  $w_0$  in second equation.
- 2. Plug solution for  $w_0$  into first equation, solve for  $w_1$ .

Solve for  $w_0$ 5= - Zy  $0 = \frac{2}{n} \sum_{i=1}^{n} \left( (w_1 x_i + w_0) - y_i \right)$ x = the Z xi  $0 = \sum w_{1} x_{1} + \sum w_{0} - \sum y_{1}$  $\Sigma w_{o} = \Sigma y_{i} - \Sigma w_{i} \times i$ nwo = Zy; - w, Z x;  $w_{o} = \frac{1}{n} \sum y_{i} - \frac{w_{i}}{n} \sum x_{i} \gg w_{o} = \overline{y} - w_{i} \overline{x}$ 

# Solve for w<sub>0</sub>

$$0 = \frac{2}{n} \sum_{i=1}^{n} \left( (w_1 x_i + w_0) - y_i \right)$$

## **Key Fact**

Then

$$\sum_{i=1}^{\infty} (x_i - \bar{x}) = 0 \qquad \sum_{i=1}^{\infty} (y_i - \bar{y}) = 0$$

## Solve for w<sub>1</sub>

# Solve for w<sub>1</sub>

$$0 = \frac{2}{n} \sum_{i=1}^{n} ((w_{1}x_{i} + w_{0}) - y_{i})x_{i} \qquad w_{0} = \bar{y} - w_{1}\bar{x}$$

$$w_{1} \sum_{i} (x_{i} - \bar{x})x_{i} - \sum_{i} (\bar{y} - y_{i})x_{i}$$

$$W_{1} = \frac{\sum_{i} (y_{i} - \bar{y})x_{i}}{\sum_{i} (x_{i} - \bar{x})x_{i}}$$

# Solve for w<sub>1</sub>

## **Least Squares Solutions**

The least squares solutions for the slope w<sub>1</sub> and intercept w<sub>0</sub> are:

where  $\bar{x} = \frac{1}{n} \sum_{i=1}^{n} x_i$   $\bar{y} = \frac{1}{n} \sum_{i=1}^{n} y_i$ 

▶ What is the sign of  $(x_i - \bar{x})(y_i - \bar{y})$  when:

 $\blacktriangleright$   $x_i > \bar{x}$  and  $y_i > \bar{y}$ ?

▶ What is the sign of  $(x_i - \bar{x})(y_i - \bar{y})$  when:

►  $x_i < \bar{x}$  and  $y_i < \bar{y}$ ?

▶ What is the sign of  $(x_i - \bar{x})(y_i - \bar{y})$  when:

►  $x_i > \bar{x}$  and  $y_i < \bar{y}$ ?

▶ What is the sign of  $(x_i - \bar{x})(y_i - \bar{y})$  when:

►  $x_i < \bar{x}$  and  $y_i > \bar{y}$ ?

## **Interpretation of Intercept**

# Question

We fit a linear prediction rule for salary given years of experience. Then everyone gets a \$5,000 raise. What happens to slope/intercept?

Example

 $\bar{x} =$ 

<u></u>*y* =

 $w_0 = \bar{y} - w_1 \bar{x}$ 

x <sub>i</sub>	Уi	$(x_i - \bar{x})$	$(y_i - \bar{y})$	$(x_i-\bar{x})(y_i-\bar{y})$	$(x_i - \bar{x})^2$
3 4 8	7 3 2				

Lecture 02 | Part 5

**Fitting Non-Linear Trends** 

## **Non-Linear Trends**

We have fit a straight line of the form:

 $H(x) = w_0 + w_1 x$ 

- What if we believe, e.g., salary grows with the square of experience?
- I.e., how do we fit a function of the form:

$$H(x) = w_0 + w_1 x^2$$
?

## "Linear" Models

- The linear in linear prediction function refers to the weights, not the features.
- ► These are all **linear** prediction functions: ►  $H(x) = w_0 + w_1 x + w_2 x^2$ ►  $H(x) = w_0 + w_1 e^x$ ►  $H(x) = w_0 + w_1 \sqrt{x} + w_2 \sin x$

These are not:
 H(x) = w<sub>0</sub> + w<sub>1</sub>e<sup>w<sub>2</sub>x</sup>
 H(x) = w<sub>0</sub> + w<sub>1</sub>sin(w<sub>2</sub>x)

## In General

- $H(x) = w_0 + w_1 \phi(x)$  is a linear model, no matter what  $\phi$  is.<sup>5</sup>
- $\phi$  is called a **basis function** (or **feature map**).
- Example:  $\phi(x) = x^2$

<sup>&</sup>lt;sup>5</sup>Provided  $\phi$  does not involve  $w_0$  and  $w_1$ 

# **Minimizing Mean Squared Error**

Fix a basis function  $\phi(x)$ .

Goal: pick w<sub>0</sub> and w<sub>1</sub> so as to minimize the mean squared error of H:

$$R_{sq}(w_0, w_1) = \frac{1}{n} \sum_{i=1}^{n} \left[ (w_0 + w_1 \phi(x_i)) - y_i \right]^2$$

# **Minimizing Mean Squared Error**

Notation: define  $z_i = \phi(x_i)$ .

Strategy: compute  $\partial R_{sq} / \partial w_0$  and  $\partial R_{sq} / \partial w_1$ , set to zero, solve.

# Solution

- Observation: This is the exact same calculation we've done, but with x<sub>i</sub> replaced by z<sub>i</sub>.
- The least squares solutions:

$$w_1 = \frac{\sum_{i=1}^n (z_i - \bar{z})(y_i - \bar{y})}{\sum_{i=1}^n (z_i - \bar{z})^2}$$

 $w_0=\bar{y}-w_1\bar{z}$ 

• where 
$$\bar{z} \equiv \frac{1}{n} \sum_{i=1}^{n} \phi(x_i)$$

## Intuition

## Interpretation

- To fit a function  $H(x) = w_0 + w_1 \phi(x)$ :
- 1. Create new data set  $\{(z_i, y_i)\}$ , where  $z_i = \phi(x_i)$ .
- 2. Fit a straight line  $H(z) = w_0 + w_1 z$  on this new data.

3. Use  $w_0$  and  $w_1$  in  $H(x) = w_0 + w_1 \phi(x)$ 

## Summary

We have seen how to fit linear prediction functions of the form:

$$H(x) = w_0 + w_1 \phi(x)$$

Next time: how do we fit functions of the form:

$$H(x_1, x_2, ...) = w_0 + w_1 \phi(x_1) + w_2 \phi(x_2) + ...$$

How does this compare to nearest neighbor methods?
