DATA STRUCTURES & ALGORITHMS

Lecture 10 | Part 1

Today's Lecture

Beyond Greedy

- ▶ Greedy algorithms are typically **fast**, but may not find the optimal answer.
- ▶ Brute force guarantees the optimal answer, but is **slow**.
- ▶ Can we guarantee the optimal answer and be faster than brute force?

Today

- ▶ The **backtracking** idea.
- ▶ It is a useful, general algorithm design technique¹.
- ▶ And the foundation of **dynamic programming**.

¹Commonly seen in tech interviews

DATA STRUCTURES & ALGORITHMS

Lecture 10 | Part 2

The 0-1 Knapsack Problem

0-1 Knapsack

- ▶ Suppose you're a thief.
- ▶ You have a knapsack (bag) that can fit 100L.
- ▶ And a list of n things to possibly steal.

| item | size (L) | price |
|---------|----------|-------|
| TV | 50 | \$400 |
| iPad | 2 | \$900 |
| Printer | 10 | \$100 |
| ⋮ | ⋮ | ⋮ |

- ▶ Goal: maximize total value of items you can fit in your knapsack.

Example

| item | size (L) | price |
|------|----------|-------|
| 1 | 50 | \$40 |
| 2 | 10 | \$25 |
| 3 | 80 | \$100 |
| 4 | 5 | \$10 |
| 5 | 20 | \$20 |
| 6 | 30 | \$6 |
| 7 | 8 | \$32 |
| 8 | 17 | \$34 |

In the bag: _____

Total value: _____

Space remaining: _____

Greedy

- ▶ Does a greedy approach find the optimal?
- ▶ What do we mean by “greedy”?
- ▶ Idea #1: take most expensive available that will fit.

Example

| item | size (L) | price |
|------|----------|-------|
| 1 | 50 | \$40 |
| 2 | 10 | \$25 |
| 3 | 80 | \$100 |
| 4 | 5 | \$10 |
| 5 | 20 | \$20 |
| 6 | 30 | \$6 |
| 7 | 8 | \$32 |
| 8 | 17 | \$34 |

In the bag: _____

Total value: _____

Space remaining: _____

Greedy, Idea #2

- ▶ We want items with high value for their size.
- ▶ Define “price density” =
`item.price / item.size`
- ▶ Idea #2: take item with highest price density.

Example

| item | size (L) | price |
|------|----------|-------|
| 1 | 50 | \$40 |
| 2 | 10 | \$25 |
| 3 | 80 | \$100 |
| 4 | 5 | \$10 |
| 5 | 20 | \$20 |
| 6 | 30 | \$6 |
| 7 | 8 | \$32 |
| 8 | 17 | \$34 |

In the bag: _____

Total value: _____

Space remaining: _____

Greedy is **Not Optimal**

- ▶ Claim: the best possible total value is \$157.
 - ▶ Items 2, 3, and 7.

Never Looking Back

- ▶ Once greedy makes a decision, it never looks back.
- ▶ This is why it may be suboptimal.
- ▶ **Backtracking**: go back to reconsider every previous decision.

DSC 190

DATA STRUCTURES & ALGORITHMS

Lecture 10 | Part 3

Backtracking

Backtracking

- ▶ Reconsider every decision.
- ▶ If we initially tried including x , also try *not* including x .

Backtracking

```
def knapsack(items, bag_size):  
    # choose item arbitrarily from those that fit in bag  
    x = items.arbitrary_item(fitting_in=bag_size)  
  
    # if None, it means there was no item that fit  
    if x is None:  
        return 0  
  
    # assume x should be in bag, see what we get  
    best_with = ...  
  
    # backtrack: now assume x should not be in bag, see what we get  
    best_without = ...  
  
    return max(best_with, best_without)
```

Recursive Subproblems

- ▶ What is $\text{BEST}(\text{items}, \text{bag_size})$ if we assume that x is in the bag?
- ▶ Imagine choosing x .
 - ▶ Your current total value is $x.\text{price}$.
 - ▶ You have $\text{bag_size} - x.\text{size}$ space left.
 - ▶ Items left to choose from: $\text{items} - x$.
- ▶ Clearly, you want the best outcome for *new* situation (subproblem).
- ▶ Answer: $x.\text{price} + \text{BEST}(\text{items} - x, \text{bag_size} - x.\text{size})$

Recursive Subproblems

- ▶ What is $\text{BEST}(\text{items}, \text{bag_size})$ if we assume that x **is not** the bag?
- ▶ Imagine deciding x is not in the bag.
 - ▶ Your current total value is v .
 - ▶ You have bag_size space left.
 - ▶ Items left to choose from: $\text{items} - x$.
- ▶ Clearly, you want the best outcome for *new* situation (subproblem).
- ▶ Answer: $v + \text{BEST}(\text{items} - x, \text{bag_size})$

Backtracking

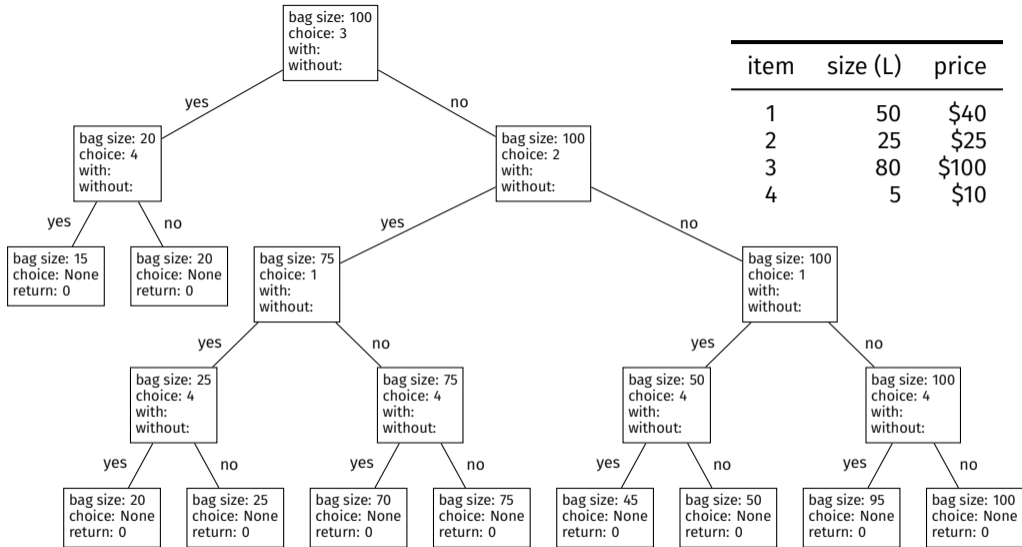

```
def knapsack(items, bag_size):  
    # choose item arbitrarily from those that fit in bag  
    x = items.arbitrary_item(fitting_in=bag_size)  
  
    # if None, it means there was no item that fit  
    if x is None:  
        return 0  
  
    # assume x is in the bag, see what we get  
    best_with = x.price + knapsack(items - x, bag_size - x.size)  
  
    # now assume x is not in bag, see what we get  
    best_without = 0 + knapsack(items - x, bag_size)  
  
    return max(best_with, best_without)
```

Backtracking

```
def knapsack(items, bag_size):  
    # choose item arbitrarily from those that fit in bag  
    x = items.arbitrary_item(fitting_in=bag_size)  
  
    # if None, it means there was no item that fit  
    if x is None:  
        return 0  
  
    items.remove(x)  
    best_with = x.price + knapsack(items, bag_size - x.size)  
    best_without = knapsack(items, bag_size)  
    items.replace(x)  
  
    return max(best_with, best_without)
```

Backtracking

- ▶ **Backtracking**: go back to reconsider every previous decision.
- ▶ Searches the whole tree.
- ▶ Can be thought of as a DFS on implicit tree.

| item | size (L) | price |
|------|----------|-------|
| 1 | 50 | \$40 |
| 2 | 25 | \$25 |
| 3 | 80 | \$100 |
| 4 | 5 | \$10 |

Exercise

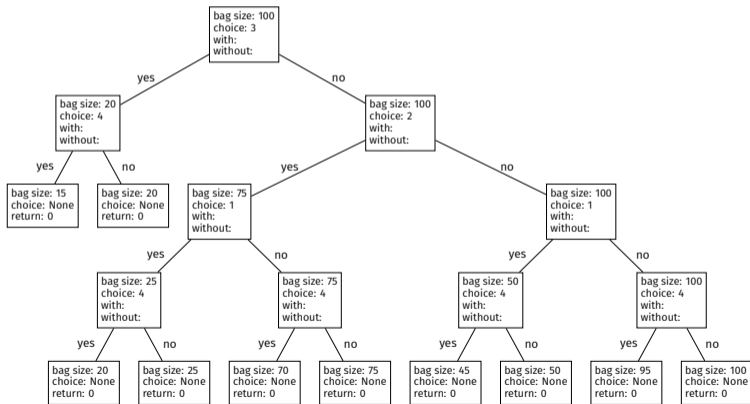

Is the backtracking solution guaranteed to find an optimal solution?

Yes!

- ▶ It tries every **valid** combination and keeps the best.
 - ▶ A combination of items is valid if they fit in the bag together.

Leaf Nodes

- ▶ Each leaf node is a different valid combination.

Exercise

Suppose instead of choosing an arbitrary node we choose most expensive. Does the answer change?

No!

- ▶ The choice of node is arbitrary.
- ▶ Call tree will change, but all valid combinations are tried.

Exercise

How does backtracking relate to the greedy approach? How would you change the code to make it greedy?

Summary

```
def knapsack_greedy(items, bag_size):  
    # choose greedily  
    x = items.most_valuable_item(fitting_in=bag_size)  
  
    # if None, it means there was no item that fit  
    if x is None:  
        return 0  
  
    # assume x is in the bag, see what we get  
    best_with = x.price + knapsack(items - x, bag_size - x.size)  
  
    # in the greedy approach, we don't do this  
    # best_without = knapsack(items - x, bag_size)  
  
    return best_with
```

DSC 190

DATA STRUCTURES & ALGORITHMS

Lecture 10 | Part 4

Efficiency Analysis

A Benchmark

- ▶ Brute force: try every **possible** combination of items.
 - ▶ Even the **invalid** ones whose total size is too big.
 - ▶ Why? Hard to know which are invalid without trying them.
- ▶ There are $\Theta(2^n)$ possible combinations.
- ▶ So brute force takes $\Omega(2^n)$ time. **Exponential** :(

Time Complexity of Backtracking

```
def knapsack(items, bag_size):  
    # choose item arbitrarily from those that fit in bag  
    x = items.arbitrary_item(fitting_in=bag_size)  
  
    # if None, it means there was no item that fit  
    if x is None:  
        return 0  
  
    items.remove(x)  
    best_with = x.price + knapsack(items, bag_size - x.size)  
    best_without = knapsack(items, bag_size)  
    items.replace(x)  
  
    return max(best_with, best_without)
```

$$T(n) =$$

Backtracking Takes **Exponential Time**

- ▶ ...in the worst case.
- ▶ This is just as bad as **brute force**.
- ▶ So why use it?
- ▶ Its worst case isn't always indicative of its practical performance.

Intuition

- ▶ Brute force tries all **possible** combinations.
- ▶ Backtracking tries all **valid** combinations.
- ▶ The number of valid combinations can be much less than the number of possible combinations.²

²Not always true!

Pruning

backtracking

brute force

Pruning

- ▶ Backtracking **prunes** branches that lead to invalid solutions.

Example

- ▶ 23 items with size/price chosen from $\text{Unif}([23, \dots, 46])$
- ▶ Bag size is 46
- ▶ Brute force: 52 seconds.
- ▶ Backtracking: 4 milliseconds.

Example

- ▶ 300 items with size/price chosen from $\text{Unif}([150, \dots, 300])$
- ▶ Bag size is 600
- ▶ Brute force: ? ($\approx 4.6 \times 10^{77}$ years)
- ▶ Backtracking: 30 seconds.

Backtracking Worst Case

- ▶ knapsack's **worst case** is when bag size is very large.
- ▶ All solutions are valid, aren't pruned.
- ▶ But this is actually an easy case!

```
def knapsack_2(items, bag_size):
    if sum(item.size for item in items) < bag_size:
        return sum(item.price for item in items)

    x = items.arbitrary_item(fitting_in=bag_size)

    if x is None:
        return 0

    items.remove(item)
    best_with = x.price + knapsack_2(items, bag_size - x.size)
    best_without = knapsack_2(items, bag_size)
    items.replace(x)

    return max(best_with, best_without)
```

Pruning

- ▶ This further prunes the tree, resulting in speedup for some inputs.

DSC 190

DATA STRUCTURES & ALGORITHMS

Lecture 10 | Part 5

Branch and Bound

Example

- ▶ Suppose you have a bag of size 100.
- ▶ One of the items is a diamond.
 - ▶ Price: \$10,000. Size: 1
- ▶ The other 49 items are coal.
 - ▶ Price: \$1. Size: 1
- ▶ Do you even consider not taking the diamond?

Idea

- ▶ Assume we take the diamond, compute best result.
- ▶ Find quick upper bound for not taking diamond.
- ▶ If upper bound is less than best for diamond, don't go down that branch.
- ▶ This is **branch and bound**; another way to prune tree.

Branch and Bound

```
def knapsack_bb(items, bag_size, find_upper_bound):  
    # try to make a good first choice  
    x = items.item_with_highest_price_density(fitting_in=bag_size)  
  
    if x is None:  
        return 0  
  
    items.remove(item)  
    best_with = x.price + knapsack_bb(items, bag_size - x.size)  
  
    if find_upper_bound(items, bag_size) < best_with:  
        best_without = 0  
    else:  
        best_without = knapsack_bb(items, bag_size)  
  
    items.replace(x)  
  
    return max(best_with, best_without)
```

Example

| item | size (L) | price |
|------|----------|--------|
| 1 | 50 | \$40 |
| 2 | 25 | \$25 |
| 3 | 95 | \$1000 |
| 4 | 5 | \$10 |

Upper Bounds for Knapsack

- ▶ How do we get a good upper bound?
- ▶ One idea: the solution to the *fractional* knapsack problem upper bounds that for 0/1 knapsack.

DSC 190

DATA STRUCTURES & ALGORITHMS

Lecture 10 | Part 6

Summary

Summary

- ▶ A backtracking approach is **guaranteed** to find an optimal answer.
- ▶ It is typically faster than brute force, but can still take **exponential time**.

Summary

- ▶ We can speed up backtracking by pruning:
- ▶ Three ways to prune:
 1. Prune invalid branches (default).
 2. Prune “easy” cases.
 3. Prune by branching and bounding.

Summary

- ▶ Next time: **dynamic programming**.
- ▶ We'll see it is just backtracking + memoization.
