

# Lecture 7 – Linear Prediction Rules

Winter 2024  
DSC 40A, ~~Spring 2023~~

# Announcements

- ▶ Homework 2 is due **today at 11:59pm**.
- ▶ Homework 3 will be posted soon.
  - ▶ Last homework before Midterm 1.

# Agenda

- ▶ Recap of convexity.
- ▶ Prediction rules.
- ▶ Minimizing mean squared error, again.

**Recap: convexity**

# Convexity: Definition

- ▶ A function  $f : \mathbb{R} \rightarrow \mathbb{R}$  is **convex** if for every choice of  $a, b$  and  $t \in [0, 1]$ :

$$(1 - t)f(a) + tf(b) \geq f((1 - t)a + tb)$$

- ▶ This means that for **every**  $a, b$  in the domain of  $f$ , the line segment between

$$(a, f(a)) \quad \text{and} \quad (b, f(b))$$

does not go below the plot of  $f$ .

# Second derivative test for convexity

- ▶ If  $f(x)$  is a function of a single variable and is twice differentiable, then:
- ▶  $f(x)$  is convex if and only if  $\frac{d^2f}{dx^2}(x) \geq 0$  for all  $x$ .
- ▶ Example:  $f(x) = x^4$  is convex.

## Discussion Question

Suppose we have a function  $f(x) = (x - a)^n$ , which of the following statement is correct?

- a)  $f(x)$  is always convex
- b)  $f(x)$  is convex if  $n$  is **odd**, non-convex if  $n$  is **even**
- c)  $f(x)$  is convex if  $n$  is **even**, non-convex if  $n$  is **odd**
- d)  $f(x)$  is always non-convex

$$f(x) = (x - a)^n$$

$$f'(x) = n(x - a)^{n-1}$$

$$f''(x) = n(n-1)(x - a)^{n-2}$$

is  $(x - 3)^{24}$  convex?

# Convexity and gradient descent

- ▶ **Theorem:** if  $R(h)$  is convex and differentiable then gradient descent converges to a **global minimum** of  $R$  *provided* that the step size is small enough.
  - ▶ If a function is **convex** and **has a local minimum**, that local minimum must be a global minimum.
  - ▶ In other words, gradient descent won't get stuck/terminate in local minimums that aren't global minimums.
- ▶ For nonconvex functions, gradient descent can still be useful, but it's not guaranteed to converge to a global minimum.

# Convexity of empirical risk

- ▶ If  $L(h, y)$  is a convex function (when  $y$  is fixed) then

$$R(h) = \frac{1}{n} \sum_{i=1}^n L(h, y_i)$$

is convex.

- ▶ More generally, sums of convex functions are convex.
- ▶ What does this mean?
  - ▶ If a loss function is convex, then the corresponding empirical risk will also be convex.

# Convexity of loss functions

$$(x-a)^n$$

- ▶ Is  $L_{\text{sq}}(h, y) = (y - h)^2$  convex? **Yes** or **No**.
- ▶ Is  $L_{\text{abs}}(h, y) = |y - h|$  convex? **Yes** or **No**.
- ▶ Is  $L_{\text{ucsd}}(h, y)$  convex? **Yes** or **No**.

# Convexity of $R_{ucsd}$

- ▶ A function can be convex in a region.
- ▶ If  $\sigma$  is large,  $R_{ucsd}(h)$  is convex in a big region around data.
  - ▶ A large  $\sigma$  led to a very smooth, parabolic-looking empirical risk function with a single local minimum (which was a global minimum).
- ▶ If  $\sigma$  is small,  $R_{ucsd}(h)$  is convex in only small regions.
  - ▶ A small  $\sigma$  led to a very bumpy empirical risk function with many local minimums.

## Discussion Question

Recall the empirical risk for absolute loss,

$$R_{abs}(h) = \frac{1}{n} \sum_{i=1}^n |y_i - h|$$

Is  $R_{abs}(h)$  **convex**? Is gradient descent **guaranteed** to find a global minimum, given an appropriate step size?

- a) **YES** convex, **YES** guaranteed
- b) **YES** convex, **NOT** guaranteed
- c) **NOT** convex, **YES** guaranteed
- d) **NOT** convex, **NOT** guaranteed

# Prediction rules

# How do we predict someone's salary?

After collecting salary data, we...

1. Choose a loss function.
  2. Find the best prediction by minimizing the average loss across the entire data set (empirical risk).
- ▶ So far, we've been predicting future salaries without using any information about the individual (e.g. GPA, years of experience, number of LinkedIn connections).
  - ▶ **New focus:** How do we incorporate this information into our prediction-making process?

# Features

A **feature** is an attribute – a piece of information.

- ▶ **Numerical**: age, height, years of experience
- ▶ **Categorical**: college, city, education level
- ▶ **Boolean**: knows Python?, had internship?

Think of features as columns in a DataFrame or table.

	YearsExperience	Age	FormalEducation	Salary
0	6.37	28.39	Master's degree (MA, MS, M.Eng., MBA, etc.)	120000.0
1	0.35	25.78	Some college/university study without earning ...	120000.0
2	4.05	31.04	Bachelor's degree (BA, BS, B.Eng., etc.)	70000.0
3	18.48	38.78	Bachelor's degree (BA, BS, B.Eng., etc.)	185000.0
4	4.95	33.45	Master's degree (MA, MS, M.Eng., MBA, etc.)	125000.0

# Variables

- ▶ The features,  $x$ , that we base our predictions on are called **predictor variables**.
- ▶ The quantity,  $y$ , that we're trying to predict based on these features is called the **response variable**.
- ▶ We'll start by predicting salary based on years of experience.

# Prediction rules

- ▶ We believe that salary is a function of experience.
- ▶ In other words, we think that there is a function  $H$  such that:  
$$\text{salary} \approx H(\text{years of experience})$$
- ▶  $H$  is called a **hypothesis function** or **prediction rule**.
- ▶ **Our goal:** find a good prediction rule,  $H$ .

# Possible prediction rules

$$H_1(\text{years of experience}) = \$50,000 + \$2,000 \times (\text{years of experience})$$

$$H_2(\text{years of experience}) = \$60,000 \times 1.05^{(\text{years of experience})}$$

$$H_3(\text{years of experience}) = \$100,000 - \$5,000 \times (\text{years of experience})$$

- ▶ These are all valid prediction rules.
- ▶ Some are better than others.

# Comparing predictions

- ▶ How do we know which prediction rule is best:  $H_1, H_2, H_3$ ?
- ▶ We gather data from  $n$  people. Let  $x_i$  be experience,  $y_i$  be salary:

$$\begin{array}{ccc} (\text{Experience}_1, \text{Salary}_1) & & (x_1, y_1) \\ (\text{Experience}_2, \text{Salary}_2) & \rightarrow & (x_2, y_2) \\ \dots & & \dots \\ (\text{Experience}_n, \text{Salary}_n) & & (x_n, y_n) \end{array}$$

- ▶ See which rule works better on data.

# Example

# Quantifying the quality of a prediction rule $H$

- ▶ Our prediction for person  $i$ 's salary is  $H(x_i)$ .
- ▶ As before, we'll use a **loss function** to quantify the quality of our predictions.
  - ▶ Absolute loss:  $|y_i - H(x_i)|$ .
  - ▶ Squared loss:  $(y_i - H(x_i))^2$ .
- ▶ We'll focus on squared loss, since it's differentiable.
- ▶ Using squared loss, the **empirical risk** (mean squared error) of the prediction rule  $H$  is:

$$R_{sq}(H) = \frac{1}{n} \sum_{i=1}^n (y_i - H(x_i))^2$$

# Mean squared error

# Finding the best prediction rule

- ▶ **Goal:** out of all functions  $\mathbb{R} \rightarrow \mathbb{R}$ , find the function  $H^*$  with the smallest mean squared error.
- ▶ That is,  $H^*$  should be the function that minimizes

$$R_{sq}(H) = \frac{1}{n} \sum_{i=1}^n (y_i - H(x_i))^2$$

## Discussion Question

Given the data below, is there a prediction rule  $H$  which has **zero** mean squared error?

a) Yes

b) No

# Problem

- ▶ We can make mean squared error very small, even zero!
- ▶ But the function will be weird.
- ▶ This is called **overfitting**.
- ▶ Remember our real goal: make good predictions on data **we haven't seen**.

Out-of-Sample Data

# Solution

- ▶ Don't allow  $H$  to be just any function.
- ▶ Require that it has a certain form.
- ▶ Examples:
  - ▶ Linear:  $H(x) = w_0 + w_1 x$ .
  - ▶ Quadratic:  $H(x) = w_0 + w_1 x + w_2 x^2$ .
  - ▶ Exponential:  $H(x) = w_0 e^{w_1 x}$ .
  - ▶ Constant:  $H(x) = w_0$ .

# Finding the best **linear** prediction rule

- ▶ **Goal:** out of all **linear** functions  $\mathbb{R} \rightarrow \mathbb{R}$ , find the function  $H^*$  with the smallest mean squared error.
  - ▶ Linear functions are of the form  $H(x) = w_0 + w_1 x$ .
  - ▶ They are defined by a slope ( $w_1$ ) and intercept ( $w_0$ ).
- ▶ That is,  $H^*$  should be the linear function that minimizes

$$R_{sq}(H) = \frac{1}{n} \sum_{i=1}^n (y_i - H(x_i))^2$$

- ▶ This problem is called **linear regression**.
  - ▶ **Simple** linear regression refers to linear regression with a single predictor variable,  $x$ .

# Minimizing mean squared error for the linear prediction rule

# Minimizing the mean squared error

- ▶ The MSE is a function  $R_{\text{sq}}$  of a function  $H$ .

$$R_{\text{sq}}(H) = \frac{1}{n} \sum_{i=1}^n (y_i - H(x_i))^2$$

- ▶ But since  $H$  is linear, we know  $H(x_i) = w_0 + w_1 x_i$ .

$$R_{\text{sq}}(w_0, w_1) = \frac{1}{n} \sum_{i=1}^n (y_i - (w_0 + w_1 x_i))^2$$

- ▶ Now  $R_{\text{sq}}$  is a function of  $w_0$  and  $w_1$ .
- ▶ We call  $w_0$  and  $w_1$  **parameters**.
  - ▶ Parameters define our prediction rule.

# Updated goal

- ▶ Find the slope  $w_1^*$  and intercept  $w_0^*$  that minimize the MSE,  $R_{\text{sq}}(w_0, w_1)$ :

$$R_{\text{sq}}(w_0, w_1) = \frac{1}{n} \sum_{i=1}^n (y_i - (w_0 + w_1 x_i))^2$$

- ▶ Strategy: multivariable calculus.

# Recall: the **gradient**

- ▶ If  $f(x, y)$  is a function of two variables, the **gradient** of  $f$  at the point  $(x_0, y_0)$  is a **vector** of **partial derivatives**:

$$\nabla f(x_0, y_0) = \begin{pmatrix} \frac{\partial f}{\partial x}(x_0, y_0) \\ \frac{\partial f}{\partial y}(x_0, y_0) \end{pmatrix}$$

- ▶ **Key Fact #1:** The derivative is to the tangent line as the gradient is to the tangent plane.

- ▶ **Key Fact #2:** The gradient points in the direction of the biggest increase.

- ▶ **Key Fact #3:** The gradient is zero at critical points.

# Minimizing multivariable functions

- ▶ From calculus, to optimize a multivariable differentiable function:
  1. Calculate the gradient vector, or vector of partial derivatives.
  2. Set the gradient equal to 0 (that is, the zero vector).
  3. Solve the resulting system of equations.

$$\begin{pmatrix} \frac{\partial f}{\partial x}(x_0, y_0) \\ \frac{\partial f}{\partial y}(x_0, y_0) \end{pmatrix} = \begin{pmatrix} 0 \\ 0 \end{pmatrix}$$

# Example

## Discussion Question

Find the point at which the function

$$f(x, y) = x^2 + y^2 - 2x - 4y$$

is minimized.

$$\begin{aligned} \frac{\partial f}{\partial x} &= (2x + 0 - 2 - 0) = 0 & \begin{cases} 2x - 2 = 0 \\ 2y - 4 = 0 \end{cases} & \Rightarrow \begin{cases} x = 1 \\ y = 2 \end{cases} \\ \frac{\partial f}{\partial y} &= (0 + 2y - 0 - 4) = 0 \end{aligned}$$

# Summary

# Summary, next time

- ▶ We introduced the linear prediction rule,  $H(x) = w_0 + w_1 x$ .
- ▶ To determine the best linear prediction rule, we'll use the squared loss and choose the one that minimizes the empirical risk, or mean squared error:

$$R_{sq}(w_0, w_1) = \frac{1}{n} \sum_{i=1}^n (y_i - (w_0 + w_1 x_i))^2$$

- ▶ **Next time:** We'll use calculus to minimize the mean squared error and find the best linear prediction rule.
  - ▶ Spoiler alert: it's the regression line, as we saw in DSC 10.
